

# SpamHam

SpamHam is a local network mock emailing website where users can send emails and a machine learning model will differentiate between it, being a spam mail, or a ham(normal) mail.

The features will include an inbox and a spam box where users will be receiving their mails.

Users while sending a mail can add the email id in the text box and the message to send and the mail will be sent to the particular user.

Websites such as:

Gmail.com

Yahoo.com

Hotmail.com

Mymail.com

popser.com

and many others use such an email classification algorithm in the backend and we will be trying our hands on it to either make it as accurate if not more.

Evaluating whether an email is spam or ham has existed for decades since the start of emailing, several research papers talk about the need for such a system back then. Now with the help of modern NLP Neural Nets we will differentiate between the emails.
